

# fn make\_stable\_truncate

Michael Shoemate

November 18, 2025

This proof resides in “**contrib**” because it has not completed the vetting process.

Proves soundness of `make_stable_truncate` in `mod.rs` at commit `f5bb719` (outdated<sup>1</sup>).

```

## Postcondition

**Theorem 1.1.** For every setting of the input parameters (`input_domain`, `input_metric`, `plan`) to `make_stable_truncate` such that the given preconditions hold,  
`make_stable_truncate` raises an error (at compile time or run time) or returns a valid transformation. A valid transformation has the following properties:

1. (Data-independent runtime errors). For every pair of members  $x$  and  $x'$  in `input_domain`, `invoke(x)`

and `invoke`( $x'$ ) either both return the same error or neither return an error.

2. (Appropriate output domain). For every member  $x$  in `input_domain`, `function`( $x$ ) is in `output_domain` or raises a data-independent runtime error.
3. (Stability guarantee). For every pair of members  $x$  and  $x'$  in `input_domain` and for every pair  $(d_{in}, d_{out})$ , where  $d_{in}$  has the associated type for `input_metric` and  $d_{out}$  has the associated type for `output_metric`, if  $x, x'$  are  $d_{in}$ -close under `input_metric`, `stability_map`( $d_{in}$ ) does not raise an error, and `stability_map`( $d_{in}$ ) =  $d_{out}$ , then `function`( $x$ ), `function`( $x'$ ) are  $d_{out}$ -close under `output_metric`.

*Appropriate Output Domain.* By line 26, the grouping keys are stable row-by-row transformations of the data, therefore the preconditions of 36 are satisfied. By the postcondition of 36, for every element  $x$  in `input_domain`, `function`( $x$ ) is in `output_domain` or raises a data-independent runtime exception.  $\square$

*Stability guarantee.* By line 60, `total_num_ids` is the total number of ids an individual may contribute to a dataset:

$$d_{SymId}(\text{function}(x), \text{function}(x')) \leq \text{total\_num\_ids}. \quad (1)$$

By the postcondition of `match_truncations`, for each `truncation_bound` on line 65,

$$\begin{aligned} \max_{id} \|d_{Sym}(\text{function}(x)_{id,g}, \text{function}(x')_{id,g})\|_\infty &\leq \text{truncation.per_group}, \\ \max_{id} \|d_{Sym}(\text{function}(x)_{id,g}, \text{function}(x')_{id,g})\|_0 &\leq \text{truncation.num_groups}, \end{aligned}$$

where  $g$  denotes the group when partitioned by `truncation_bound.by`.

The preconditions of 68 are satisfied on line 69 (`id_bound.by` is equal to `truncation.by`), so by the postcondition of `truncate_id_bound`,

$$\begin{aligned} \|d_{Sym}(\text{function}(x)_g, \text{function}(x')_g)\|_\infty &\leq \text{row_bound.per_group}, \\ \|d_{Sym}(\text{function}(x)_g, \text{function}(x')_g)\|_0 &\leq \text{row_bound.num_groups}, \end{aligned}$$

where `row_bound` denotes the return value.

For each truncation on line 65, `truncate_id_bound` on line 68 computes upper bounds on the resulting distance between adjacent datasets. All acquired bounds are valid upper bounds on the distance between the two datasets, by the postcondition of `match_truncations`, that each truncation does not invalidate the truncation bounds of the previous truncations.

It is shown that for every pair of elements  $x, x'$  in `input_domain` and for every pair  $(d_{in}, d_{out})$ , where  $d_{in}$  has the associated type for `input_metric` and  $d_{out}$  has the associated type for `output_metric`, if  $x, x'$  are  $d_{in}$ -close under `input_metric`, `stability_map`( $d_{in}$ ) does not raise an exception, and `stability_map`( $d_{in}$ )  $\leq d_{out}$ , then `function`( $x$ ), `function`( $x'$ ) are  $d_{out}$ -close under `output_metric`.  $\square$
