# fn make\_count

Sílvia Casacuberta, Grace Tian, Connor Wagaman

This proof resides in "contrib" because it has not completed the vetting process.

Proves soundness of make\_count in mod.rs at commit f5bb719 (outdated<sup>1</sup>).

make\_count returns a Transformation that computes a count of the number of records in a vector. The length of the vector, of type usize, is exactly casted to a user specified output type TO. If the length is too large to be represented exactly by TO, the cast saturates at the maximum value of type TO.

## 1 Hoare Triple

### Precondition

- TIA (atomic input type) is a type with trait Primitive. Primitive implies TIA has the trait bound:
  - CheckNull so that TIA is a valid atomic type for AtomDomain
- TO (output type) is a type with trait Number. Number further implies TO has the trait bounds:
  - InfSub so that the output domain is compatible with the output metric
  - CheckNull so that TO is a valid atomic type for AtomDomain
  - ExactIntCast for casting a vector length index of type usize to TO. ExactIntCast further implies
     TO has the trait bound:
    - \* ExactIntBounds, which gives the MAX\_CONSECUTIVE value of type TO
  - One provides a way to retrieve TO's representation of 1
  - DistanceConstant to satisfy the preconditions of new\_stability\_map\_from\_constant

#### Pseudocode

```
def make_count(
   input_domain: VectorDomain[AtomDomain[TIA]],
   input_metric: SymmetricDistance

):
   output_domain = AtomDomain(TO) #

def function(data: Vec[TIA]) -> TO: #
   size = input_domain.size(data) #
   try: #
   return TO.exact_int_cast(size) #
```

#### Postcondition

Theorem 1.1. For every setting of the input parameters (TIA, TO) to make\_count such that the given preconditions hold, make\_count raises an exception (at compile time or run time) or returns a valid transformation. A valid transformation has the following properties:

- 1. (Appropriate output domain). For every element x in input\_domain, function(x) is in output\_domain or raises a data-independent runtime exception.
- 2. (Stability guarantee). For every pair of elements x, x' in input\_domain and for every pair (d\_in, d\_out), where d\_in has the associated type for input\_metric and d\_out has the associated type for output\_metric, if x, x' are d\_in-close under input\_metric, stability\_map(d\_in) does not raise an exception, and stability\_map(d\_in)  $\leq$  d\_out, then function(x), function(x') are d\_out-close under output\_metric.

## 2 Proofs

Proof. (Part 1 – appropriate output domain). The output\_domain is AtomDomain(T0), so it is sufficient to show that function always returns non-null values of type T0. By the definition of the ExactIntCast trait, T0.exact\_int\_cast always returns a non-null value of type T0 or raises an exception. If an exception is raised, the function returns T0.MAXIMUM\_CONSECUTIVE, which is also a non-null value of type T0. Thus, in all cases, the function (from line 9) returns a non-null value of type T0.

Before proceeding with proving the validity of the stability map, we provide a couple lemmas.

**Lemma 2.1.**  $|function(u) - function(v)| \le |len(u) - len(v)|$ , where len is an alias for input\_domain.size.

Proof. By CollectionDomain, we know size on line 8 is of type usize, so it is non-negative and integral. Therefore, by the definition of ExactIntCast, the invocation of T0.exact\_int\_cast on line 10 can only fail if the argument is greater than T0.MAX\_CONSECUTIVE. In this case, the value is replaced with T0.MAX\_CONSECUTIVE. Therefore, function(u) = min(len(u), c), where c = T0.MAX\_CONSECUTIVE. We use this equality to prove the lemma:

```
| \mathtt{function}(u) - \mathtt{function}(v) | = | \min(\mathtt{len(u)}, c) - \min(\mathtt{len(v)}, c) |
\leq | \mathtt{len(u)} - \mathtt{len(v)} | \qquad \text{since clamping is stable}
```

**Lemma 2.2.** For vector v with each element  $\ell \in v$  drawn from domain  $\mathcal{X}$ ,  $len(v) = \sum_{z \in \mathcal{X}} h_v(z)$ .

*Proof.* Every element  $\ell \in v$  is drawn from domain  $\mathcal{X}$ , so summing over all  $z \in \mathcal{X}$  will sum over every element  $\ell \in x$ . Recall that the definition of SymmetricDistance states that  $h_v(z)$  will return the number of occurrences of value z in vector v. Therefore,  $\sum_{z \in \mathcal{X}} h_v(z)$  is the sum of the number of occurrences of each unique value; this is equivalent to the total number of items in the vector.

Since CollectionDomain is implemented for VectorDomain<AtomDomain<TIA», we depend on the correctness of the implementation Conditioned on the correctness of the implementation of CollectionDomain for VectorDomain<AtomDomain<TIA», the variable size is of type usize containing the number of elements in arg. Therefore,  $\sum_{z \in \mathcal{X}} h_v(z)$  is equivalent to size.

*Proof.* (Part 2 – stability map). Take any two elements u, v in the input\_domain and any pair (d\_in,d\_out), where d\_in has the associated type for input\_metric and d\_out has the associated type for output\_metric. Assume u, v are d\_in-close under input\_metric and that stability\_map(d\_in)  $\leq$  d\_out. These assumptions are used to establish the following inequality:

$$\begin{split} |\mathsf{function}(u) - \mathsf{function}(v)| &\leq |\mathsf{len}(\mathsf{u}) - \mathsf{len}(\mathsf{v})| & \text{by 2.1} \\ &= |\sum_{z \in \mathcal{X}} h_\mathsf{u}(z) - \sum_{z \in \mathcal{X}} h_\mathsf{v}(z)| & \text{by 2.2} \\ &= |\sum_{z \in \mathcal{X}} (h_\mathsf{u}(z) - h_\mathsf{v}(z))| & \text{by algebra} \\ &\leq \sum_{z \in \mathcal{X}} |h_\mathsf{u}(z) - h_\mathsf{v}(z)| & \text{by triangle inequality} \\ &= d_{Sym}(u,v) & \text{by SymmetricDistance} \\ &\leq \mathsf{d_in} & \text{by the first assumption} \\ &\leq \mathsf{T0.inf\_cast}(\mathsf{d_in}) & \text{by InfCast} \\ &\leq \mathsf{T0.one}().\mathsf{inf\_mul}(\mathsf{T0.inf\_cast}(\mathsf{d_in})) & \text{by InfMul} \\ &= \mathsf{stability\_map}(\mathsf{d_in}) & \text{by pseudocode line 16} \\ &< \mathsf{d\_out} & \text{by the second assumption} \end{split}$$

It is shown that function(u), function(v) are d\_out-close under output\_metric.
