# fn truncate\_id\_bound

## Michael Shoemate

April 29, 2025

This proof resides in "contrib" because it has not completed the vetting process.

Proves soundness of truncate\_id\_bound in mod.rs at commit f5bb719 (outdated<sup>1</sup>). truncate\_id\_bound returns an uppper bound on dataset distances in terms of the symmetric distance metric.

# 1 Hoare Triple

### Precondition

#### Caller Verified

• id\_bound.by = truncate.by

#### **Function**

```
def truncate_id_bound(
      id_bound: Bound,
      truncation: Bound,
      total_ids: Optional[int],
  ) -> Bound:
      # Once truncated, max contributions when grouped by "over" are bounded
      row_bound = Bound.by(truncation.by)
      # In each group, the worst-case row contributions is the
      # the number of ids contributed (known from id_bound)
10
      # times the number of rows contributed under each id (known from truncation),
11
      num_ids, num_rows = id_bound.per_group, truncation.per_group
12
      if num_ids is not None and num_rows is not None:
13
14
          row_bound = row_bound.with_per_group(num_ids.inf_mul(num_rows)) #
15
      # Worst case number of groups contributed is the
      # total number of ids contributed (total_ids)
17
      # times the number of groups contributed under each id (known from truncation).
18
      num_groups_via_truncation = None #
19
      if total_ids is not None and truncation.num_groups is not None:
20
21
          num_groups_via_truncation = total_ids.inf_mul(truncation.num_groups)
22
      # Alternatively, the number of groups contributed may be known outright from id_bound.
      # Use the smaller of the two if both are known.
24
      num_groups = option_min(num_groups_via_truncation, id_bound.num_groups)
26
      if num_groups is not None:
          row_bound = row_bound.with_num_groups(num_groups) #
27
```

#### Postcondition

**Theorem 1.1** (Postcondition). Let g vary over groups when partitioned by id\_bound.by. If for any two datasets x, x' we have that

```
||d_{\text{SymId}}(\text{function}(x)_q, \text{function}(x')_q)||_{\infty} \leq \text{id\_bound.per\_group},
 ||d_{\text{SymId}}(\text{function}(x)_q, \text{function}(x')_q)||_0 \leq \text{id\_bound.num\_groups},
          d_{\text{SymId}}(\text{function}(x), \text{function}(x')) < \text{total_ids},
```

and function truncates a dataset such that,

$$\max_{id} ||d_{\mathrm{Sym}}(\mathtt{function}(x)_{id,g},\mathtt{function}(x')_{id,g})||_{\infty} \leq \mathtt{truncation.per\_group},$$

$$\max_{id} ||d_{\mathrm{Sym}}(\mathtt{function}(x)_{id,g},\mathtt{function}(x')_{id,g})||_{0} \leq \mathtt{truncation.num\_groups},$$

then we have that

$$||d_{\mathrm{Sym}}(\mathtt{function}(x)_g,\mathtt{function}(x')_g)||_{\infty} \leq \mathtt{row\_bound.per\_group}, \\ ||d_{\mathrm{Sym}}(\mathtt{function}(x)_g,\mathtt{function}(x')_g)||_{0} \leq \mathtt{row\_bound.num\_groups},$$

where row\_bound denotes the return value.

*Proof.* Assume the preconditions are met, as well as the conditions of the postcondition. We first prove the per-group bound.

```
||d_{\mathrm{Sym}}(\mathtt{function}(x)_g,\mathtt{function}(x')_g)||_{\infty}
\leq ||d_{\operatorname{SymId}}(\operatorname{function}(x)_g,\operatorname{function}(x')_g)||_{\infty} \cdot \max_{i,d} ||d_{\operatorname{Sym}}(\operatorname{function}(x)_{id,g},\operatorname{function}(x')_{id,g})||_{\infty}
≤ id_bound.per_group · truncation.per_group
                                                                  by line 14
= row_bound.per_group
```

We now prove the number of groups bound. There are two ways to bound the number of contributed groups. We first reason by the total number of identifiers.

```
||d_{\text{Sym}}(\text{function}(x)_q, \text{function}(x')_q)||_0
\leq d_{\operatorname{SymId}}(\mathtt{function}(x),\mathtt{function}(x')) \cdot \max_{i,d} ||d_{\operatorname{Sym}}(\mathtt{function}(x)_{id,g},\mathtt{function}(x')_{id,g})||_0
 \leq total_ids \cdot truncation.num_groups
                                                                      by line 19
 = num_groups_via_truncation
```

We can also directly bound the number of contributed groups by id\_bound.num\_groups:

```
||d_{\mathrm{Sym}}(\mathtt{function}(x)_g,\mathtt{function}(x')_g)||_0
 = ||d_{\text{SymId}}(\text{function}(x)_g, \text{function}(x')_g)||_0
 \leq {\tt id\_bound.num\_groups}
```

This is a valid upper bound on the number of contributed groups, because truncation is applied independently to each group.

Therefore, we take the minimum of the two upper bounds.

```
||d_{\text{Sym}}(\text{function}(x)_q, \text{function}(x')_q)||_0
min(num_groups_via_truncation, id_bound.num_groups)
= row_bound.num_groups
                                            by line 27
```

In the implementation, any of the input bounds could be missing. When a bound is missing, any output bounds that require it are not claimed.
