fn make_float_to_bigint

Michael Shoemate

This proof resides in "contrib" because it has not completed the vetting process.

Proves soundness of the implementation of make_float_to_bigint in mod.rs at commit f5bb719 (out-dated¹).

1 Hoare Triple

Precondition

Compiler-Verified

- Generic T implements trait Float
- Const-generic P is of type usize
- Generic QI implements trait Number
- Type RBig implements traits TryFrom<T> and TryFrom<QI>. This is for fallible exact casting to rationals from floats in the function and input sensitivity in the privacy map.
- Type i32 implements trait ExactIntCast«T as FloatBits>::Bits>, This requirement means that the raw bits of T can be exactly cast to an i32.

Postcondition

Theorem 1.1.

Theorem 1.2. For every setting of the input parameters (input_space, k, T, P, QI) to make_float_to_bigint such that the given preconditions hold, make_float_to_bigint raises an exception (at compile time or run time) or returns a valid transformation. A valid transformation has the following properties:

- 1. (Appropriate output domain). For every element x in input_domain, function(x) is in output_domain or raises a data-independent runtime exception.
- 2. (Stability guarantee). For every pair of elements x, x' in input_domain and for every pair (d_in, d_out), where d_in has the associated type for input_metric and d_out has the associated type for output_metric, if x, x' are d_in-close under input_metric, stability_map(d_in) does not raise an exception, and stability_map(d_in) \leq d_out, then function(x), function(x') are d_out-close under output_metric.

Proof. In the definition of the function on line 16, RBig.try_from is infallible when the input is non-nan making the function infallible. Line 14 checks that k is not i32.MIN, which satisfies the precondition for find_nearest_multiple_of_2k on line 18, and ensures that negation is well-defined on line 25. There are no other sources of error in the function, so the function cannot raise data-dependent errors.

The function also always returns a vector of IBigs, of the same length as the input, meaning the output of the function is always a member of the output domain, as defined on line 29.

The stability argument breaks down into three parts:

• The casting from float to rational on line 17 is 1-stable, because the real values of the numbers remain un-changed, meaning the distance between adjacent inputs always remains the same.

• The rounding on line 18 can cause an increase in the sensitivity equal to $n^{1/p} \cdot (2^k - 2^{k_{min}})$.

$$\max_{x \sim x'} d_{Lp}(f(x), f(x')) \tag{1}$$

$$= \max_{x \sim x'} |\operatorname{round}_k(x) - \operatorname{round}_k(x')|_p \tag{2}$$

$$\leq \max_{x \sim x'} |(x+2^{k-1}) - (x'-2^{k-1}+2^{k_{min}})|_p \tag{3}$$

$$\leq \max_{x \sim x'} |x - x'|_p + |1_n \cdot (2^k - 2^{k_{min}})|_p \tag{4}$$

$$= \max_{x \sim x'} d_{Lp}(x, x') + n^{1/p} \cdot (2^k - 2^{k_{min}})$$
 (5)

$$= d_{in} + n^{1/p} \cdot (2^k - 2^{k_{min}}) \tag{6}$$

This increase in the sensitivity is reflected on line 25, which, by the postcondition of get_rounding_distance, returns the maximum increase in sensitivity due to rounding, matching the above analysis.

• The discarding of the denominator on line 18 is 2^k -stable, as the denominator is 2^k . This increase in sensitivity is also reflected on line 25, where the sensitivity is multiplied by a factor of 2^{-k} .

For every pair of elements x, x' in input_domain and for every pair (d_{in}, d_{out}) , where d_{in} has the associated type for input_metric and d_{out} has the associated type for output_metric, if x, x' are d_{in} -close under input_metric, stability_map(d_{in}) does not raise an exception, and stability_map(d_{in}) $\leq d_{out}$, then function(x), function(x') are d_{out} -close under output_metric.
