# fn make\_laplace

## Michael Shoemate

This proof resides in "contrib" because it has not completed the vetting process.

Proves soundness of the implementation of make\_laplace in mod.rs at commit f5bb719 (outdated<sup>1</sup>). Perturbative noise mechanisms may be parameterized along many different axes:

- domain: scalar or vector
- domain dtype: i8, i16, i32, i64, u8, u16, u32, u64, f32, f64, UBig, IBig, RBig
- metric: absolute distance, 11 distance, modular distance
- metric dtype: i8, i16, i32, i64, u8, u16, u32, u64, f32, f64, UBig, IBig, RBig
- measure: max divergence, zero concentrated divergence
- distribution: laplace, gaussian

All parameterizations reduce to a single core mechanism that perturbs a vector of signed big integers with noise sampled from the appropriate discrete distribution.

The implementation of this function constructs a random variable denoting the noise distribution to add, and then dispatches to the MakeNoise<DI, MI, MO> trait which constructs the core mechanism and wraps it in pre-processing transformations and post-processors to match the desired parameterization.

# 1 Hoare Triple

### Precondition

### Compiler-Verified

- generic DI implements trait Domain
- generic MI implements trait Metric
- generic MO implements trait Measure
- type DiscreteLaplace implements trait MakeNoise<DI, MI, MO> This trait bound constrains the choice of input domain, input metric and output measure to those that can form valid measurements.
- type (DI, MI) implements trait MetricSpace

## Pseudocode

```
def make_laplace(
 input_domain: DI,
 input_metric: MI,
 scale: f64,
 k: Option[i32],
) -> Measurement[DI, DI_Carrier, MI, MO]:
 return DiscreteLaplace(scale, k).make_noise((input_domain, input_metric))
```

## Postcondition

#### Theorem 1.1.

Theorem 1.2. For every setting of the input parameters (input\_domain, input\_metric, scale, k, DI, MI, MO) to make\_laplace such that the given preconditions hold, make\_laplace raises an exception (at compile time or run time) or returns a valid measurement. A valid measurement has the following property:

1. (Privacy guarantee). For every pair of elements x, x' in input\_domain and for every pair  $(d_in, d_out)$ , where d\_in has the associated type for input\_metric and d\_out has the associated type for output\_measure, if x, x' are d\_in-close under input\_metric, privacy\_map(d\_in) does not raise an exception, and privacy\_map(d\_in)  $\leq$  d\_out, then function(x), function(x') are d\_out-close under output\_measure.

*Proof.* We first construct a random variable DiscreteLaplace representing the desired noise distribution. Since MakeNoise.make\_noise has no preconditions, the postcondition follows, which matches the postcondition for this function.
