fn make_vec

Michael Shoemate

Proves soundness of the implementation of `make_vec` in `mod.rs` at commit f5bb719 (outdated[1]).

This transformation simply wraps an input scalar in a singleton vec. The output metric then becomes an Lp distance.

Precondition

Compiler-Verified

- Generic `T` implements trait `Number`

- Generic `Q` implements trait `Number`

User-Verified

None

Pseudocode

```
def make_vec(
    input_space: tuple[AtomDomain[T], AbsoluteDistance[Q]],
) -> Transformation[
    AtomDomain[T], VectorDomain[AtomDomain[T]], AbsoluteDistance[Q], LpDistance[P, Q]
]:
    input_domain, input_metric = input_space
    return Transformation.new(
        input_domain,
        VectorDomain.new(input_domain).with_size(1),
        lambda arg: [arg],
        input_metric,
        LpDistance.default(),
        lambda d_in: d_in,
    )
```

Postcondition

Theorem 1.1.

Theorem 1.2. For every setting of the input parameters (`input_space`, `T`, `Q`) to `make_vec` such that the given preconditions hold, `make_vec` raises an error (at compile time or run time) or returns a valid transformation. A valid transformation has the following properties:

---

[1]See new changes with `git diff f5bb719..cabbe21 rust/src/transformations/scalar_to_vector/mod.rs`

1. (Data-independent runtime errors). For every pair of members x and x' in `input_domain`, `invoke`(x) and `invoke`(x') either both return the same error or neither return an error.

2. (Appropriate output domain). For every member x in `input_domain`, `function`(x) is in `output_domain` or raises a data-independent runtime error.

3. (Stability guarantee). For every pair of members x and x' in `input_domain` and for every pair (`d_in`, `d_out`), where `d_in` has the associated type for `input_metric` and `d_out` has the associated type for `output_metric`, if x, x' are `d_in`-close under `input_metric`, `stability_map(d_in)` does not raise an error, and `stability_map(d_in)` = `d_out`, then `function`(x), `function`(x') are `d_out`-close under `output_metric`.

Proof. The function is infallible, and the output domain trivially follows, since all output vectors are length-one. For all x in the input domain, the output of `make_vec` is a vector of length 1, so the output domain is trivially valid. The function is 1-stable because:

$$\texttt{d\_out} \tag{1}$$

$$= \max_{x \sim x'} d_{Lp}(f(x), f(x')) \tag{2}$$

$$= \max_{x \sim x'} (\sum_i (x_i - x_i')^p)^{1/p} \tag{3}$$

$$= \max_{x \sim x'} ((x_1 - x_1')^p)^{1/p} \tag{4}$$

$$= \max_{x \sim x'} |x_1 - x_1'| \tag{5}$$

$$= \max_{x \sim x'} d_{Abs}(x_1, x_1') \tag{6}$$

$$= 1 \cdot \texttt{d\_in} \tag{7}$$

$$\tag{8}$$

For every pair of elements x, x' in `input_domain` and for every pair (`d_in`, `d_out`), where `d_in` has the associated type for `input_metric` and `d_out` has the associated type for `output_metric`, if x, x' are `d_in`-close under `input_metric`, `stability_map(d_in)` does not raise an exception, and `stability_map(d_in)` $\leq$ `d_out`, then `function`(x), `function`(x') are `d_out`-close under `output_metric`. $\qquad\square$
