> This proof resides in **"contrib"** because it has not completed the vetting process.

This document proves soundness of `peel_permute_and_flip` in `mod.rs` at commit e62b0aa2 (outdated[1]). `peel_permute_and_flip` noisily selects the index of the greatest score from a vector of input scores k times without replacement.

1 Hoare Triple

Preconditions

Types consistent with pseudocode.

Pseudocode

```
 1  def peel_permute_and_flip(
 2      x: list[RBig],
 3      scale: RBig,
 4      k: usize,
 5      replacement: bool,
 6  ):
 7      natural_order = []
 8      sorted_order = BTreeSet.new()
 9
10      for _ in range(min(k, x.len())):
11          index = permute_and_flip(x, scale, replacement)   #
12          x.remove(index)   #
13
14          # map index on modified x back to original x (postprocessing)
15          for del_ in sorted_order:   # |
16              if del_ <= index:
17                  index += 1
18              else:
19                  break
20
21          sorted_order.insert(index)
22          natural_order.push(index)
23
24      return natural_order
```

Postcondition

Theorem 1.1. • If replacement is set, returns a sample from $\mathcal{M}_{EM}$ (as defined in MS2023 Definition 4), otherwise returns a sample from $\mathcal{M}_{PF}$ (as defined in MS2023 Lemma 1), k times by peeling, where $\texttt{scale} = \frac{2 \cdot \Delta}{\epsilon}$.

- Errors are data-independent, except for exhaustion of entropy.

Proof. The pseudocode applies `permute_and_flip` on line 11 up to k times (no greater than the number of scores), each time removing the selected score on line 12.

Since the index in subsequent selections may be offset by an earlier removal, a data-independent post-processing of the index is performed on line 15.

The only source of error is due to entropy exhaustion. $\qquad\qquad\square$
