fn make_geometric

Michael Shoemate

> This proof resides in **"contrib"** because it has not completed the vetting process.

Proves soundness of the implementation of `make_geometric` in `mod.rs` at commit f5bb719 (outdated[1]).

The implementation of this function constructs a random variable denoting the noise distribution to add, and then dispatches to the `MakeNoise<DI, MI, MO>` trait which constructs the core mechanism and wraps it in pre-processing transformations and post-processors to match the desired parameterization.

1 Hoare Triple

Precondition

Compiler-Verified

- generic `DI` implements trait `Domain`

- generic `MI` implements trait `Metric`

- generic `MO` implements trait `Measure`

- type `DiscreteLaplace` implements trait `MakeNoise<DI, MI, MO>`

- type `ConstantTimeGeometric` implements trait `MakeNoise<DI, MI, MO>` These traits constrain the choice of input domain, input metric and output measure to those that can form valid measurements when adding noise from these distributions.

- type `(DI, MI)` implements trait `MetricSpace`

Pseudocode

```
1  def make_geometric(
2      input_domain: DI,
3      input_metric: MI,
4      scale: f64,
5      bounds: Option[tuple[DI_Atom, DI_Atom]],
6  ) -> Measurement[DI, DI_Carrier, MI, MO]:
7      input_space = input_domain, input_metric
8      if bounds is None:
9          return DiscreteLaplace(scale, k=None).make_noise(input_space)
10     else:
11         return ConstantTimeGeometric(scale, bounds).make_noise(input_space)
```

Postcondition

Theorem 1.1. For every setting of the input parameters (`input_domain, input_metric, scale, bounds, DI, MI, MO`) to `make_geometric` such that the given preconditions hold, `make_geometric` raises an exception (at compile time or run time) or returns a valid measurement. A valid measurement has the following properties:

1. (Data-independent runtime errors). For every pair of elements x, x' in `input_domain`, $\texttt{function}(x)$ returns an error if and only if $\texttt{function}(x')$ returns an error.

2. (Privacy guarantee). For every pair of elements x, x' in `input_domain` and for every pair $(\texttt{d\_in}, \texttt{d\_out})$, where `d_in` has the associated type for `input_metric` and `d_out` has the associated type for `output_measure`, if x, x' are `d_in`-close under `input_metric`, $\texttt{privacy\_map}(\texttt{d\_in})$ does not raise an exception, and $\texttt{privacy\_map}(\texttt{d\_in}) \leq \texttt{d\_out}$, then $\texttt{function}(x), \texttt{function}(x')$ are `d_out`-close under `output_measure`.

Proof. If bounds are supplied, this constructor builds a specialized mechanism that adds noise to the input data from the ConstantTimeGeometric random variable. Otherwise noise is added from the DiscreteLaplace random variable, which uses a logarithmic-time discrete laplace sampling algorithm.

Since MakeNoise.`make_noise` has no preconditions, the postcondition follows, which matches the postcondition for this function. □
