> This proof resides in **"contrib"** because it has not completed the vetting process.

This document proves soundness of `permute_and_flip` [2] in `mod.rs` at commit e62b0aa2 (outdated[1]). `permute_and_flip` noisily selects the index of the greatest score from a vector of input scores.

## 1 Hoare Triple

### Preconditions

*Types consistent with pseudocode.*

### Pseudocode

```python
def permute_and_flip(x: list[RBig], scale: RBig):
    if scale.is_zero():   #
        return max(range(x.len()), key=lambda i: x[i])

    # begin nonzero scale
    x_max = max(x)
    permutation = list(range(x.len()))

    for left in range(x.len()):
        right = left + sample_uniform_uint_below(x.len() - left)
        permutation.swap(left, right) # fisher-yates shuffle up to left

        candidate = permutation[left]
        if sample_bernoulli_exp((x_max - x[candidate]) / scale):
            return candidate

    raise "at least one x[candidate] is equal to x_max"
```

### Postcondition

**Theorem 1.1.** Returns the index of the max element $z_i$, where each $z_i \sim \text{Exp}(\text{shift} = x_i, \text{scale} = \texttt{scale})$.

**Lemma 1.2.** The permute-and-flip mechanism is equivalent to the report-noisy-max with exponential noise mechanism.

See [1] for proof of Lemma 1.2.

**Lemma 1.3.** The pseudocode starting from line 5 equivalent to Algorithm 1 in [2], where $\texttt{scale} = \frac{2\Delta}{\epsilon}$.

---

[1] See new changes with `git diff e62b0aa2..4850993 rust/src/measurements/noisy_top_k/exponential/mod.rs`

*Proof.* By swapping elements on line 11, an online Fisher-Yates shuffle is applied up to and including index `left`.

Substituting `scale` $= \frac{2\Delta}{\epsilon}$, the argument to `sample_bernoulli_exp` is then $\frac{\epsilon}{2\Delta}(q_* - q_r)$, which is non-negative, satisfying the precondition of `sample_bernoulli_exp`. Therefore by the postcondition of `sample_bernoulli_exp`, the response is a sample from $\mathrm{Bern}(\exp(-x))$, where $x = \frac{\epsilon}{2\Delta}(q_* - q_r)$. Therefore the response is a sample from $\mathrm{Bern}(\exp\left(\frac{\epsilon}{2\Delta}(q_r - q_*)\right))$, which is equivalent to Algorithm 1 in [2]. $\qquad\square$

*Proof of Theorem 1.1.* Consider two cases: zero scale and nonzero scale. When scale is zero on line 2, each $z_i = x_i$, so the argmax is returned. Otherwise, by Lemma 1.3 the pseudocode is equivalent to Algorithm 1 in [2], which is in turn equivalent to the postcondition by Lemma 1.2. In all two cases, the postcondition holds. $\qquad\square$
